Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids Institute of Medicine, Food and Nutrition Board, Standing Committee on the Scientific Evaluation of Dietary Reference Intakes, Subcommittee on Interpretation and Uses of Dietary Reference Intakes, Subcommittee on Upper Reference Levels of Nutrients, Panel on the Definition of Dietary Fiber, Panel on Macronutrients, 2005-11-28 Responding to the expansion of scientific knowledge about the roles of nutrients in human health, the Institute of Medicine has developed a new approach to establish Recommended Dietary Allowances (RDAs) and other nutrient reference values. The new title for these values Dietary Reference Intakes (DRIs), is the inclusive name being given to this new approach. These are quantitative estimates of nutrient intakes applicable to healthy individuals in the United States and Canada. This new book is part of a series of books presenting dietary reference values for the intakes of nutrients. It establishes recommendations for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids. This book presents new approaches and findings which include the following: The establishment of Estimated Energy Requirements at four levels of energy expenditure Recommendations for levels of physical activity to decrease risk of chronic disease The establishment of RDAs for dietary carbohydrate and protein The development of the definitions of Dietary Fiber, Functional Fiber, and Total Fiber The establishment of Adequate Intakes (AI) for Total Fiber The establishment of AIs for linolenic and α -linolenic acids Acceptable Macronutrient Distribution Ranges as a percent of energy intake for fat, carbohydrate, linolenic and α -linolenic acids, and protein Research recommendations for information needed to advance understanding of macronutrient requirements and the adverse effects associated with intake of higher amounts Also detailed are recommendations for both physical activity and energy

expenditure to maintain health and decrease the risk of disease.

Energy Intake and Activity Ernesto Pollitt, Peggy Amante, 1984 Abstract: A collection of 18 authoritative review papers, taken from a series of related workshops, addresses various aspects of the association of energy intake with physical activity. The papers are organized among 5 general topic areas, including energy balance studies concerning the association of inappropriate energy intakes with adaptation and reproductive competence of populations; methodological issues concerning energy balance studies and data in both adults and children; the effects of reduced energy intake on agricultural productivity, activity and metabolism, motor development, and sleep; and microeconomic and other consequences and policy implications of reduced activity and energy intake deficiencies.

The Intraday Relation Between Physical Activity and Dietary Intake Among Behavioral Weight Loss

Participants Rebecca Jane Crochiere, 2022 Weight control (weight loss/maintenance) is determined by energy balance, i.e., the difference between energy intake (from food and beverage consumption) and energy expenditure (from resting metabolic rate and physical activity [PA]). Energy balance typically is most strongly influenced by energy intake (as compared to PA), and it remains unknown whether engaging in PA, a central component of most behavioral weight loss programs, increases, decreases, or has no effect on same-day energy intake among individuals with overweight/obesity pursuing weight loss. Findings from the extant literature in this area are mixed, and more importantly, the methodology and design of existing studies (e.g., using healthy-weight samples, laboratory-based settings, and correlation designs that lack temporal precedent) make their findings inapplicable to the current research question. The current study addressed this gap in the literature by using technology that can measure PA and diet in individuals' every-day lives to examine how engaging in PA is associated with same-day energy intake among behavioral weight loss participants. Participants were 101 adults with overweight/obesity enrolled in a weight loss program instructed to follow a reduced-calorie diet and PA prescription. At mid-treatment, PA was measured via a wrist-worn accelerometer (Fitbit Charge) and dietary intake via a self-monitoring app (MyFitnessPal Premium) for 3 weeks. Multilevel models were used to examine the within-person, intraday relations between PA and dietary intake, including energy, macronutrient, and sugar intake. Specifically, the current study examined the relation between PA and the dietary intake preceding PA (pre-PA), acutely following PA (acute post-PA, i.e., in the 2 hours following PA), in the remaining time in day following the acute post-PA period (remaining time in day), and across entire PA days (full-day), relative to non-PA matched time periods. Two definitions of PA were used, moderate-to-vigorous PA (MVPA) and any-intensity PA, which includes light, moderate, and vigorous PA. Primary aims showed energy intake was higher in the acute post-PA period (for MVPA only) but lower in the remaining time in day (both MVPA and any-intensity PA) relative to non-PA matched time periods. Energy intake also was higher in the pre-PA period (both MVPA and any-intensity PA), though there was no difference in full-day energy intake on entire PA days versus non-PA days. In general, protein, fat, carbohydrate, and sugar consumption increased or decreased commensurately with energy intake post-PA (i.e., increased in the acute post-PA period and decreased in the remaining time in day). The relation between PA and same-day energy intake was moderated by several factors, including BMI, time of day of PA, hunger post-exercise, and the perception of having engaged in exercise. There was little evidence to suggest energy intake pre-PA, post-PA, or across entire PA days, relative to non-PA matched time periods, had a relation with percent weight change. Taken together, these findings support that engaging in PA versus not is associated with different within-person dietary patterns and those relations are moderated by biological, contextual, and psychological variables; however, there was insufficient evidence to support that observed deviations in energy intake on PA versus non-PA days are associated with weight change.

Energy Balance in Motion Klaas R. Westerterp, 2012-12-13 Energy balance can be maintained by adapting energy intake to changes in energy expenditure and vice versa, where short-term changes in energy expenditure are mainly caused by physical activity. Questions are whether physical activity is affected by over and under-eating, is intake affected by an increase or a decrease in physical activity, and does overweight affect physical activity? Presented evidence is largely based on studies where physical activity is quantified with doubly labeled water. Overeating does not affect physical activity while under-eating decreases habitual or voluntary physical activity. Thus, it is easier to gain weight than to lose weight. An exercise induced increase in energy requirement is compensated by intake while a change to a more sedentary routine does not induce an equivalent reduction of intake and generally results in weight gain. Overweight and obese subjects have similar activity energy expenditures than lean people despite they move less. There are two options to reverse the general population trend for an increasing body weight, reducing intake or increasing physical activity. Based on the results presented, eating less is most effective for preventing weight gain, despite a potential negative effect on physical activity when reaching a negative energy balance.
