How the Mountains Grew John Dvorak, 2021-08-03 The incredible story of the creation of a continent—our continent—from the acclaimed author of *The Last Volcano* and *Mask of the Sun*. The immense scale of geologic time is difficult to comprehend. Our lives—and the entirety of human history—are mere nanoseconds on this timescale. Yet we hugely influenced by the land we live on. From shales and fossil fuels, from lake beds to soil composition, from elevation to fault lines, what could be more relevant than the history of the ground beneath our feet? For most of modern history, geologists could say little more about why mountains grew than the obvious: there were forces acting inside the Earth that caused mountains to rise. But what were those forces? And why did they act in some places of the planet and not at others? When the theory of plate tectonics was proposed, our concept of how the Earth worked experienced a momentous shift. As the Andes continue to rise, the Atlantic Ocean steadily widens, and Honolulu creeps ever closer to Tokyo, this seemingly imperceptible creep of the Earth is revealed in the landscape all around us. But tectonics cannot—and do not—explain everything about the wonders of the North American landscape. What about the Black Hills? Or the walls of chalk that stand amongst the rolling hills of west Kansas? Or the fact that the states of Washington and Oregon are slowly rotating clockwise, and there a diamond mine in Arizona? It all points to the geologic secrets hidden inside the 2-billion-year-old continental masses. A whopping ten times older than the rocky floors of the ocean, continents hold the clues to the long history of our planet. With a sprightly narrative that vividly brings this science to life, John Dvorak's *How the Mountains Grew* will fill readers with a newfound appreciation for the wonders of the land we live on.

Magmatic Processes at Mid-ocean Ridges Rachel E. Sours-Page, 2000 Magmatic processes control the chemical compositions of all lavas erupted at mid-ocean ridges. In this thesis, I present studies of magmatic processes on three different mid-ocean ridges to determine which processes are in action and to what extent each has affected the chemistry of mid-ocean ridge basalts at each location. On the Endeavour Segment, Juan de Fuca Ridge, major and trace element data from enriched and depleted lavas and melt inclusions indicate that lavas and melt inclusions are the results of partial melting of a heterogeneous source. Trace element models suggest that depleted lavas are formed from variable degrees of partial melting of a refractory harzburgite source, while enriched lavas result from very small degrees of melting of a clinopyroxenite source. Major and trace element data from axial and seamount lavas and melt inclusions from the northern East Pacific Rise indicate that chemical differences between axial and seamount magmas result from varying exposure to crustal and axial magma chamber processes. Seamount lavas and inclusions are more crystal rich and contain a greater number of inclusions that are generally more primitive and exhibit a larger compositional range in both the incompatible and trace elements. Seamount lavas leave the axial magma chamber before axial lavas, and thereby miss the further fractionation and crystal sorting. Major element data from Southeast Indian Ridge lavas suggest that the dominant control of MORB chemistry is mantle temperature. Lavas from this region range from high Na, low Fe in the east to low Na, high Fe₈ in the west, suggestive of higher high Na₈, low Fe₈ in the east to low Na₈, high Fe₈ in the west, suggestive of higher pressures and extents of melting in the western part of the study area. Variable degrees and pressures of melting are consistent with a mantle temperature gradient which extends from hot mantle below the Amsterdam-St Paul hotspot to cold mantle below the Australian-Antarctic Discordance.

The Subseafloor Biosphere at Mid-Ocean Ridges William S. D. Wilcock, 2004-01-09 Published by the American Geophysical Union as part of the Geophysical Monograph Series, Volume 144. Awareness has grown over the past several years that the subseafloor may harbor a substantial biosphere sustained by volcanic heat and chemical fluxes from the Earth's interior. This realization has profound scientific implications for questions concerning the origins of life, the true extent of Earth's biosphere, and the search for life on other planets. At mid-ocean spreading centers, the fluxes that sustain life are the highest, and the hydrothermal fluids in which micro-organisms grow are readily accessible on the seafloor. In addition, periodic volcanic eruptions flush fluids and microbes from the subsurface, and volcanic gases are believed to drive spectacular microbial blooms. Although ridges are challenging locations in which to work, they are unique in the oceans because of the diversity and dynamic nature of their subsurface environments.

Magmatic Processes and Plate Tectonics H. M. Prichard,1993 This volume celebrates Professor Ian Gass, covering many of the subjects which most interested him, especially processes operating in oceanic crust. The introductory papers examine evolution of magmas from mantle melting to eruption. A central section concerns ophiolite complexes. Several papers focus on different aspects of the Troodos ophiolite complex in Cyprus. In addition, ophiolites are reviewed and examined. A further section concentrates on tectonics and the genesis of magmas associated with collision and subduction. This contrasts with continental rifting and the effects of mantle plumes.
